6.1 – Placement
Perlite concrete should be conveyed from the mixer to the place of final deposit by methods which will prevent segregation or loss of material. Equipment for conveying perlite concrete should be designed to ensure delivery without separation of materials or serious loss of air content. Pumping should be in accordance with recommendations of the perlite producer, and the perlite concrete shall meet the specified properties at the point of placement.

Perlite concrete should be deposited and screeded in a continuous operation until the placing of a panel or section is completed.

Expanded polystyrene board should be placed in a minimum 3.1 mm wet slurry of insulating concrete. It is recommended the board be covered by perlite concrete to finished thickness before the slurry is set.

6.2 – Curing
Normal Conditions: Perlite concrete has an adequate mixing water content so as to have sufficient water for proper curing of the concrete without additional precautions. Under these conditions the concrete should be permitted to air dry.

Extreme Dry Conditions: When perlite concrete is placed during extreme dry weather, additional water may have to be sprinkled on the concrete for a sufficient period of time to allow hydration of the concrete.

Cold Weather Conditions: For winter pouring the use of high early strength (Type III) Portland cement is recommended. All concrete materials, reinforcement and forms with which the perlite concrete may come in contact should be free of frost. No frozen material or materials containing ice should be used. When it is anticipated outside temperature will be below 4°C, 24 hours after placing of the concrete, the mixing water should be heated to a maximum of 48°C. Perlite insulating concrete should not be placed during freezing weather unless the contractor is experienced in the special techniques required.

The built-up roofing should be applied as soon as the perlite insulating concrete can carry construction traffic, and is dry enough to develop adhesion with hot asphalt or pitch. Roof application should proceed when the perlite concrete has been cured a minimum of three days. Provision shall be made for perimeter or edge venting by use of an open metal gravel guard or facia.

6.3.1 – Mechanical Fasteners
Nailing or stapling are preferred methods of attachment for the base sheet, and shall be used on perlite concrete applied over structural concrete.

RECOMMENDED PRACTICES FOR WORKMANSHIP AND TOLERANCES

7.1 – Variation of Plane
Variation in deck thickness should be no greater than 6.5 mm on a 3m straight edge.

This tolerance does not include variations resulting from substrate.

7.2 – Variation in Deck Thickness
Variation in deck thickness should be no greater than 6.5 mm from specified thickness established by averaging measurements taken at 3 points on a 3m x 3m square.

7.3 – Rain or Freezing Damage Before Setting of Concrete
It is recommended the deck be allowed to cure for a minimum of three days.

After freezing or heavy rainfall give a thorough brooming if required before roofing.

That portion of the deck which has excessive sealing should be removed to solid concrete, and patched.

Path additives may be used at the applicator's option. If minor scaling occurs broom surface before roofing.

Perlite concrete exposed to extreme cold after setting will provide adequate strength to receive roofing if not subjected to mechanical damage. Therefore, all traffic should be prohibited.

Damage after placement caused by other trades should not be the responsibility of the applicator.
**INSTALLATION**

### 6.1 – Placement

Perlite concrete should be conveyed from the mixer to the place of final deposit by methods which will prevent segregation or loss of material. Equipment for conveying perlite concrete should be designed to ensure delivery without separation of materials or serious loss of air content.

Pumping should be in accordance with recommendations of the perlite producer, and the perlite concrete shall meet the specified properties at the point of placement.

Perlite concrete should be deposited and screeded in a continuous operation until the placing of a panel or section is completed.

Expanded polystyrene board should be placed in a minimum 3.1 mm wet slurry of insulating concrete.

It is recommended the board be covered by perlite concrete to finished thickness before the slurry is set.

### 6.2 – Curing

**Normal Conditions:** Perlite concrete has an adequate mixing water content so as to have sufficient water for proper curing of the concrete without additional precautions. Under these conditions the concrete should be permitted to air dry.

**Extreme Dry Conditions:** When perlite concrete is placed during extreme dry weather, additional water may have to be sprinkled on the concrete for a sufficient period of time to allow hydration of the concrete.

**Cold Weather Conditions:** For winter pouring the use of high early strength (Type III) Portland cement is recommended. All concrete materials, reinforcement and forms with which the perlite concrete may come in contact should be free of frost. No frozen material or materials containing ice should be used. When it is anticipated outside temperature will be below 4°C. 24 hours after placing of the concrete, the mixing water should be heated to a maximum of 48°C.

Perlite insulating concrete should not be placed during freezing weather unless the contractor is experienced in the special techniques required.

The built-up roofing should be applied as soon as the perlite insulating concrete can carry construction traffic, and is dry enough to develop adhesion with hot asphalt or pitch.

Roof application should proceed when the perlite concrete has been cured a minimum of three days. Provision shall be made for perimeter or edge venting by use of an open metal gravel guard or fascia.

### 6.3.1 – Mechanical Fasteners

Nailing or stapling are preferred methods of attachment for the base sheet, and shall be used on perlite concrete applied over structural concrete.
1.1 – Scope
This document brings together pertinent information on the design and placement of perlite insulating concrete. The use of this information is for perlite concrete applicators responsible for the installation and application of perlite insulating concrete.

1.2 – Definition
Perlite insulating concrete is a combination of perlite aggregate, Portland cement, air entraining agent, water and/or other additives producing a concrete with an oven dry density of 800 kg/m³ or less.

1.3 – Usage
Field placed perlite insulating concrete is commonly used for insulating roof decks, fills and other semi-structural insulation applications.

Perlite insulating concrete roof decks may also employ expanded polystyrene insulation board which is embedded in the concrete.

1.4 – Applicable ASTM Standards
C 150: Specifications for Portland Cement
C 332: Specifications for Lightweight Aggregates for Insulating Concrete
C 495: Method of Test for Compressive Strength of Lightweight Insulating Concrete
C 513: Method of Securing, Preparing and Testing Specimens from Hardened Lightweight Insulating Concrete

2.1 – Perlite Aggregate
Perlite aggregate conforming to ASTM Designation C 332, Group I.

2.2 – Cement
Portland cement conforming to ASTM Designation C 150, either Type I, Type II or Type III.

2.3 – Air Entraining Agent or Other Additives
It is recommended that the perlite aggregate manufacturer be consulted for information and data.

2.4 – Water
Water should be clean and free of deleterious substances.

2.5 – Control Joints
Shall be a highly compressible vapour permeable material which will compress to one half its thickness under a load of 172 kPa or less.

2.6 – Embedded Insulation
Shall be expanded polystyrene insulation board with a minimum density of 16 kg/m³.

2.7 – Reinforcing Mesh
Shall be a galvanized wire mesh with a minimum cross sectional area of 0.17cm².

3.1 – Compressive Strength
Should be determined in accordance with ASTM Designation C 495.

3.2 – Mechanical Fasteners
Perlite insulating concrete has a nailability capacity suitable for the mechanical attachment of the base ply of built-up roofing [18.2 kg minimum nail pull]. ES Nail-Tite MK III (Zono-Tite nails, Simplex Tube Lok nails, E.G. Insuldeck Loc-nails, or Berryfast Tape/Staple systems are suitable fasteners for this purpose.

3.3 – Oven Dry Unit Weight
Oven dry weight is a measure of the insulation value of the perlite concrete and may be determined in accordance with ASTM Designation C 495.

4.1 – Control Joints
It is recommended that at least a 25mm control joint be provided through the thickness of the perlite concrete at the junction of all roof projections and parapet walls.*

This should be increased to 37.5mm for roof areas over 30m in length.

This recommendation assumes that suitable consideration has been given to the use of adequate through-building control joints.

*This recommendation does not apply when the roof deck is designed as a diaphragm to resist horizontal forces and galvanized corrugated metal form units are employed.
PROPORTIONING AND MIX DESIGN

5.2 – Air Entraining Agent
The use of the correct amount of air entraining agent is very important in successful perlite concrete construction. The air entraining agent produces countless tiny air bubbles in the concrete which reduces the density, increases the yield and contributes to the insulation factor of the dry concrete.

5.3 – Job Mixing
Perlite insulating concrete should be mixed in a mechanical mixer designed expressly for lightweight insulating concrete. The required amount of water as specified or predetermined for the batch is placed in the mixer, followed by the air entraining solution, cement and perlite aggregate. The batch is then mixed until workable (approximately 1½ to 3 minutes). Check wet density for conformance to specification range, discharge and place immediately. Mixing time is governed by the type of equipment used and can be determined by checking the wet density of the perlite concrete at intervals until the specified wet density is reached.

5.4 – Yield Calculation
Yield is defined as the ratio between the volume of the wet perlite concrete as discharged from the mixer and the volume of perlite concrete aggregate used in the mix. The mix proportions included in Table 5.1 are based on extensive field and laboratory tests and are established for 100% yield.

If the correct quantities of materials and mixing procedure are used, a 100% yield should result. 100% of yield is of importance from the standpoint of economy and physical properties of the dry concrete.

5.4.1 – Yield Check for Wet Density
The first step necessary in making a field check for yield is to determine the wet density of the perlite insulating concrete. Wet density can be checked beginning with the first batch mixed. Adjustments to the mixing procedure should be made at that time and additional checks made from time to time during pouring.

A simple method of field checking wet density is as follows:
1. Determine the exact volume of a cylindrical container such as a 10 litre bucket. This can be done by first weighting the bucket empty, then filling it level full with water and weighing it again and subtracting the bucket weight. This gives the net weight of the volume of water, and if divided by the density of the water, the result is the exact volume of the container.
This document brings together pertinent information on the usage of perlite insulating concrete roof decks.

1.3 – Usage

Water should be clean and free of deleterious substances. Consult the manufacturer for information and data.

Perlite insulating concrete roof decks may also employ either Type I, Type II or Type III cement. Consult the manufacturer for information and data.

2.2 – Cement

Perlite insulating concrete should be mixed in a mechanical mixer. The required amount of water as specified or predetermined is then mixed until workable (approximately 1 1/2 to 3 minutes). The result is the wet density of the perlite concrete in Kg/m³.

EXAMPLE:

Weight of empty bucket: 0.9 kg
Weight of bucket filled with water: 10.5 kg
Net weight of water: 9.6 kg

Volume = Net Weight of water
Density of water: 1000 kg/m³

= 9.6 kg

= 0.01 m³

2. Fill the container with the wet perlite concrete and weigh again. Subtract the weight of the empty bucket and divide the remainder by the volume as determined in Step I above. The result is the wet density of the perlite concrete in Kg/m³:

EXAMPLE:

A mix with typical wet density range of 650kg +/- 32kg (a 1.6 mix ratio)

Weight of bucket and perlite concrete: 7.4 kg
Weight of empty bucket: 0.9 kg
Weight of perlite concrete: 6.5 kg

Wet density = Weight of perlite concrete
Volume

= 6.5 kg

0.01 m³

= 650 kg/m³

5.4.3 – Loss of Yield

If the yield as checked by the wet density method is LESS than 100%, a “loss of yield” is evident. A loss of yield may be attributed to one or more of the following factors which should be checked:

1. Air Entraining Agent: Be sure that the proper type and amount of air entraining solution is being added to each mix.

2. Mixing Procedure and Time: Be sure that the materials are added to the mixer in the proper order. Undermixing of the perlite concrete will usually result in a loss of yield. Overmixing can adversely affect air entrainment.

3. Water: Check the quantity of water added to the mix. After about one minute of mixing, properly proportioned perlite concrete often looks too dry and field personnel add water for plasticity. Extra water sometimes reduces yield. Usually hard water offsets the effects of the air entraining agent, and the perlite manufacturer should be consulted for additional air entraining recommendations.

4. Types of Bases: In some cases even though the yield of the perlite concrete is correct as discharged for the mixer, more materials are required for the job than estimated. When estimating the cubic metres of perlite concrete required, consideration must be given to the type of base used. Some bases sag slightly between supports and additional concrete is required to give a level top surface; others allow small quantities of the concrete to drop through and be wasted. Depending on the type of base used, an average concrete thickness should be used for estimating and a small addition made for waste.
This document brings together pertinent information on Perlite Insulating Concrete (PICR) for construction purposes.

1. **Scope**
   - **General**
     - It is recommended that the perlite aggregate manufacturer be consulted for additional air entraining agent.

2. **Usage**
   - Water should be clean and free of deleterious substances.

3. **Materials**
   - **Portland Cement**:
     - Cement shall be a conforming to ASTM Designation C 150, Type I.
   - **Cement Additives**:
     - Air entraining agent shall be a Type II or III Portland cement to enhance freeze-thaw resistance.
   - **Perlite Aggregate**:
     - Perlite aggregate conforming to ASTM Designation C 332, Group I.
     - Shall be a highly compressible vapour permeable material with a minimum density of 16 kg/m³.
   - **Expanded Polystyrene Board**:
     - Shall be placed in a minimum thickness of 50mm.
   - **PERLITE**:
     - Shall be a galvanized wire mesh with a minimum cross section of 0.17mm.
   - **Concrete**:
     - Concrete shall be a minimum density of 800 kg/m³ or less.
   - **Insulating Concrete**:
     - Insulating concrete should be designed to ensure delivery segregation or loss of material.
     - Equipment for conveying the place of final deposit by methods which will prevent segregation or loss of material.

4. **Preparation**
   - **Mixing**:
     - The first step necessary in making a field check for yield is to determine the exact volume of a cylindrical container used to check the wet density of the perlite concrete at intervals after the first batch mixed. Adjustments to the mixing procedure such as a 10 litre bucket can be done by first pouring the correct volume of water and weighing it again and subtracting the bucket weight. This gives the net weight of the volume of water, water and weighing it again and subtracting the bucket weight. This gives the net weight of the volume of water, this weight divided by the density of water: 1000 kg/m³.
   - **Yield Check for Wet Density**:
     - EXAMPLE:
     - **Volume**: 0.01 m³
     - **Wet Density of Perlite Concrete**: 6.5 kg
     - **Weight of Bucket and Perlite Concrete**: 7.4 kg
     - **Weight of Bucket Filled with Water**: 10.5 kg
     - **Oven Dry Unit Weight**
       - **Volume**: 0.01 m³
       - **Volume of Water**: 0.01 m³
       - **Weight of Water**: 10.0 kg
   - ** Yield %**
     - **Yield Check for Wet Density**
       - **(b):         0.170**
       - **EXAMPLE**
       - **(b):         0.170**
       - **(b):         0.170**
     - **Yield %**: __________ x 100 = 100%**

5. **Curing**
   - **Normal Conditions**:
     - Perlite concrete has an adequate mixing to finished thickness before the slurry is set.
   - **Extreme Dry Conditions**:
     - Extreme dry weather, additional water may have to be attributed to one or more of the following factors which is recommended the deck be allowed to cure for a minimum of three days.
     - When perlite concrete is placed below 4°C. 24 hours after placing of the concrete, the mixing gravel guard or facia. That portion of the deck which has excessive sealing should be the responsibility of the applicator.
     - Therefore, all traffic should be prohibited.

6. **Additional Information**
   - **Environment**:
     - After freezing or heavy rainfall give a thorough brooming if required. If the concrete has been placed in freezing weather unless the contractor is experienced in the use of adequate through-building frost. No frozen material or materials containing ice should be provided through the thickness of the perlite concrete at the junction of all roof projections and parapet walls.
     - **PERMILL**:
       - Shall be a galvanized wire mesh with a minimum cross section of 0.17mm.
       - Shall be a highly compressible vapour permeable material with a minimum density of 16 kg/m³.
